<b>AIM:</b>	To implement N Queens problem
<b>PROBLEM STATEMENT :</b>	To implement N Queens problem using backtracking
<b>ALGORITHM/ THEORY:</b>	<p>The goal of the N Queens problem is to arrange N queens on a NxN chessboard so that no two queens threaten one other. In other words, no two queens may be in the same row, column, or diagonal at the same time. Backtracking, a general algorithmic approach that includes systematically trying out different solutions and undoing those that don't work until a solution is discovered, can be used to solve the problem.</p> <p><b>Algorithm:</b></p> <ol style="list-style-type: none"> <li>1. Start in the leftmost column</li> <li>2. If all queens are placed, return true</li> <li>3. Try all rows in the current column. For each row: <ol style="list-style-type: none"> <li>a. If the queen can be placed safely in this row and column, mark this cell and recursively try to place the rest of the queens on the board</li> <li>b. If the placement leads to a solution, return true</li> <li>c. If the placement doesn't lead to a solution, unmark this cell and try the next row</li> </ol> </li> <li>4. If all rows have been tried and nothing worked, return false to trigger backtracking to the previous column</li> <li>5. Repeat steps 3-4 for the previous column, trying the next row until a solution is found or all solutions have been tried</li> </ol> <p>The time complexity of the N Queens problem using backtracking is <math>O(N!)</math>, where N is the size of the board.</p> <p>This is because there are <math>N!</math> possible ways to place N queens on an NxN board, and the backtracking algorithm tries all of them.</p>

**PROGRAM:**

```
#include <stdio.h>
#include <stdlib.h>

int n;

int check(int row, int col, int (*arr)[n])
{
    for (int i = 0; i < col; i++)
    {
        if (arr[row][i])
        {
            return 0;
        }
    }

    for (int i = row, j = col; i >= 0 && j >= 0; i--, j--)
    {
        if (arr[i][j])
        {
            return 0;
        }
    }

    for (int i = row, j = col; j >= 0 && i < n; i++, j--)
    {
        if (arr[i][j])
        {
            return 0;
        }
    }

    return 1;
}

int queens(int col, int (*arr)[n])
{
    if (col >= n)
    {
        return 1;
    }

    for (int i = 0; i < n; i++)
    {
        if (check(i, col, arr))
        {
            arr[i][col] = 1;

            if (queens(col + 1, arr))
            {
                return 1;
            }
        }
    }
}
```

```

        arr[i][col] = 0;
    }
}

return 0;
}

void printBoard(int (*arr)[n])
{
    for (int i = 0; i < n; i++)
    {
        for (int j = 0; j < n; j++)
        {
            printf("\t%d ", arr[i][j]);
        }
        printf("\n\n");
    }
}

int main()
{
    printf("No. of Queens(n): ");
    scanf("%d", &n);
    int arr[n][n];
    for (int i = 0; i < n; i++)
    {
        for (int j = 0; j < n; j++)
        {
            arr[i][j] = 0;
        }
    }
    if (queens(0, arr))
    {
        printf("\nSolution:\n");
        printBoard(arr);
    }
    else
    {
        printf("\nSolution doesn't exist.\n");
    }

    return 0;
}

```

**RESULT:**

● \* Executing task: /usr/bin/clang /Users/stephen03/Dev/repos/stepDAA/exp7/q2.c -o ../excs/q2 && ../excs/q2

No. of Queens(n): 4

Solution:

0	0	1	0
1	0	0	0
0	0	0	1
0	1	0	0

\* Terminal will be reused by tasks, press any key to close it

**CONCLUSION:**

Successfully understood N Queens problem and its implementation using Backtracking in C
